

Torus

both axes wrap: the highest band's row meets the lowest

Cylinder

columns wrap; the frequency axis is open, as in the cochlea

Sheet

nothing wraps; coupling stops at every edge

Sphere

rows are latitudes, poles open; columns are longitudes that wrap

Helix

all 256 sites in one closed ring, four rows (one octave) per turn; each row runs on into the next; one turn joins bands an octave apart (± 64 sites)

Cube

each row's 16 columns fold into a 4×4 slab; all three axes wrap; columns 0-3, 4-7, 8-11 and 12-15 are the four lines of each row's slab

Coil

all 256 sites in one open line, apex (lowest band) to base (highest), one octave per turn; each row runs on into the next; one turn (± 64 sites) joins adjacent turns; the ends never meet

Cochlea

the coil; influence runs base to apex three to one, and coupling grows with curvature toward the apex

Left: a channel's 16×16 grid; glued edges share a colour and an arrow, dark edges are open, grey edges are explained below the grid. Right: the shape the gluing makes. Colour: the mel band that drives each row (lowest dark, highest yellow). Star: one oscillator. Dots: its nearest neighbours under that geometry.
